## 2. Arithmetic Progression: nth terms of A.P

$$
a_{n}=a+(n-1) d
$$

1. Find the $20^{\text {th }}$ term from the last term of the AP: $3,8,13, \ldots, 253$.

Solution: We have, last term =1=253
And, common difference $d=2^{\text {nd }}$ term $-1^{\text {st }}$ term $=8-3=5$
Therefore, $20^{\text {th }}$ term from end $=1-(20-1) \times \mathrm{d}=253-19 \times 5=253-95$ $=158$.
2. Find the number of natural numbers between 101 and 999 which are divisible by both 2 and 5 .

Solution:
Natural numbers between 101 and 999 divisible by both 2 and 5 are 110, 120, ... 990.
so, $a_{1}=110, d=10, a_{n}=990$
We know, $a_{n}=a_{1}+(n-1) d$
$990=110+(\mathrm{n}-1) 10$
( $\mathrm{n}-1$ ) $=990-11010$
$\Rightarrow \mathrm{n}=88+1=89$.
3. Find how many integers between 200 and 500 are divisible by 8 .

Solution:
AP formed is $208,216,224, \ldots, 496$
Here, $a_{n}=496, a=208, d=8$
$a_{n}=a+(n-1) d$
$\Rightarrow 208+(\mathrm{n}-1) \times 8=496$
$\Rightarrow 8(\mathrm{n}-1)=288$
$\Rightarrow \mathrm{n}-1=36$
$\Rightarrow \mathrm{n}=37$.
4. How many terms of the AP $18,16,14, \ldots$. be taken so that their sum is zero?

Solution:
Here, $\mathrm{a}=18, \mathrm{~d}=-2, \mathrm{~s}_{\mathrm{n}}=0$
Therefore, $n 2[36+(n-1)(-2)]=0$
$\Rightarrow \mathrm{n}(36-2 \mathrm{n}+2)=0$
$\Rightarrow \mathrm{n}(38-2 \mathrm{n})=0$
$\Rightarrow \mathrm{n}=19$.
5. Which term of the AP: $3,8,13,18, \ldots$, is 78 ?

Solution:
Let $a_{n}$ be the required term and we have given AP
$3,8,13,18, \ldots .$.
Here, $a=3, d=8-3=5$ and $\mathrm{a}_{\mathrm{n}}=78$

Now, $\mathrm{a}_{\mathrm{n}}=\mathrm{a}+(\mathrm{n}-1) \mathrm{d}$
$\Rightarrow 78=3+(\mathrm{n}-1) 5$
$\Rightarrow 78-3=(\mathrm{n}-1) \times 5$
$\Rightarrow 75=(\mathrm{n}-1) \times 5$
$\Rightarrow 755=\mathrm{n}-1$
$\Rightarrow 15=\mathrm{n}-1$
$\Rightarrow \mathrm{n}=15+1=16$
Hence, $16^{\text {th }}$ term of given AP is 78 .

## Practice:

6. Find the 9th term from the end (towards the first term) of the A.P. 5, 9,13,185.(ans: 153).

## 3. Arithmetic Progression: Sum of nth terms.

$$
\mathrm{S}_{\mathrm{n}}=\frac{n}{2}[2 \mathrm{a}+(\mathrm{n}-1) \mathrm{d}] \& \mathrm{~S}_{\mathrm{n}}=\frac{n}{2}[\mathrm{a}+\mathrm{l}]
$$

1. Find the sum of the A.P: $1,3,5$, 199.

Solution: $\mathrm{a}=1, \mathrm{~d}=2$ and last term $\mathrm{l}=199$

$$
\begin{aligned}
& \mathrm{a}_{\mathrm{n}}=\mathrm{a}+(\mathrm{n}-1) \mathrm{d} \\
& \Rightarrow 199=1+(\mathrm{n}-1) \times 2 \\
& \Rightarrow 2 \mathrm{n}=200 \\
& \mathrm{n}=100 \\
& \begin{aligned}
\therefore \mathrm{Sum} & =\frac{n}{2}[\mathrm{a}+1] \\
& =\frac{100}{2}[1+199] \\
& =10000
\end{aligned}
\end{aligned}
$$

2. Find the sum of the series $51+50+49+--------+21$.

Solution: $\mathrm{a}=51, \mathrm{~d}=-1$ and last term $\mathrm{l}=21$
$\mathrm{a}_{\mathrm{n}}=\mathrm{a}+(\mathrm{n}-1) \mathrm{d}$
$\Rightarrow 21=51+(\mathrm{n}-1) \times-1$
21 $=51+1$-n
$\Rightarrow \mathrm{n}=52-21$
$\mathrm{n}=31$
$\therefore$ sum $=\frac{n}{2}[a+1]$
$=\frac{31}{2}[51+21]=\frac{31}{2}[72]$
$=1116$
3. How many terms of the AP $18,16,14, \ldots$ be taken so that their sum is zero?
Solution:
Here, $\mathrm{a}=18, \mathrm{~d}=-2, \mathrm{~s}_{\mathrm{n}}=0$
Therefore, $\frac{n}{2}[36+(\mathrm{n}-1)(-2)]=0$
$\Rightarrow \mathrm{n}(36-2 \mathrm{n}+2)=0$
$\Rightarrow \mathrm{n}(38-2 \mathrm{n})=0$
$\Rightarrow \mathrm{n}=19$
4. Find the sum of first 22 terms of an AP in which $\boldsymbol{d}=7$ and $22^{\text {nd }}$ term is 149 .
Solution: Given,
Common difference, $\mathrm{d}=7$
$22^{\text {nd }}$ term, $\mathrm{a}_{22}=149$
To find: Sum of first 22 term, $\mathrm{S}_{22}$
By the formula of nth term, we know;

$$
a_{n}=a+(n-1) d
$$

$\mathrm{a}_{22}=\mathrm{a}+(22-1) \mathrm{d}$
$149=a+21 \times 7$
$149=a+147$
a = 2 = First term
Sum of nth term is given by the formula;
$\mathrm{S}_{\mathrm{n}}=\mathrm{n} / 2\left(\mathrm{a}+\mathrm{a}_{\mathrm{n}}\right)$
$=22 / 2(2+149)$
$=11 \times 151$
$=1661$
5. Find the sum of first 20 natural numbers which are divisible by 4.

Solution: The A.P which are divisible by 4 is $4,8,12, \ldots \ldots$
Here we have to find $a_{n} . a=4, d=4$

$$
\begin{gathered}
\mathrm{a}_{\mathrm{n}}=\mathrm{a}+(\mathrm{n}-1 \mathrm{~d}) \\
\mathrm{a}_{20}=4+19 \mathrm{x} 4 \\
\mathrm{a}_{20}=4+76 \\
\mathrm{a}_{20}=80 . \\
\therefore \text { sum }=\frac{n}{2}[\mathrm{a}+1] \\
=\frac{20}{2}[4+80] \\
=10 \mathrm{x} 84 \\
=840 .
\end{gathered}
$$

\end{aligned}
$$

$$
\begin{equation*}
A B=B C=\sqrt{106} \tag{i}

$$

$\therefore \quad \mathrm{ABC}$ is an isosceles $\triangle$.

$$
\begin{aligned}

3. Draw a line segment of length 8.3 cm and divide it in the ratio 2:5.

4. Draw a line segment $\mathrm{PQ}=8.4 \mathrm{~cm}$. Divide PQ into four equal parts using ruler and compass.

5. Draw a line segment of length 7.6 cm divide it in the ratio 3:5.

## Practice:

6. Draw a line of length 7 cm , divide it in the ratio $2: 4$.
7. Draw a line segment then divide internally in the ratio of 3:7.
8. Draw a line segment $\mathrm{AB}=10 \mathrm{~cm}$ \& divide it in the ratio $5: 8$.
9. Draw a line of length 7.3 cm and then divide it in the ratio $4: 6$.
10. Draw a line segment of $\mathrm{AB}=8 \mathrm{~cm}$ and divide it in the ratio $3: 2$ by geometrical construction.
11. Construct a tangent to a circle of radius 4 cm at any point P on its circumference.

## 8. Constructions: Tangent construction

1. Construct tangents to a circle of radius 5 cm such that the angle between the tangents is $60^{\circ}$.

2. Construct a circle of radius 4.5 cm , such that the angle between the two radii is $135^{\circ}$.

3. Draw a circle with the help of a bangle. Take a point outside the circle.

Construct the pair of tangents from this point to the circle.

4. Construct a tangent to a circle of radius 4 cm from a point on the concentric circle of radius 6 cm and measure its length.

Justification:
In $\triangle \mathrm{BPO}$, we have
$\angle B P O=90^{\circ}, O B=6 \mathrm{~cm}$ and $\mathrm{OP}=4 \mathrm{~cm}$
$\therefore \mathrm{OB}^{2}=\mathrm{BP}^{2}+\mathrm{OP}^{2}$ [Using Pythagoras theorem]
$\Rightarrow B P=\sqrt{O B^{2}-O P^{2}}$
$\Rightarrow B P=\sqrt{36-16}=\sqrt{20} \mathrm{~cm}=4.47 \mathrm{~cm}$
Similarly, $B Q=4.47 \mathrm{~cm}$
5. Draw a line segment $A B$ of length 8 cm . Taking $A$ as centre, draw a circle of radius 4 cm and taking $B$ as centre, draw another circle of radius 3 cm . Construct tangents to each circle from the centre of the other circle.

Justification:
On joining BP, we have $\angle \mathrm{BPA}=90^{\circ}$, as $\angle \mathrm{BPA}$ is the angle in the semicircle.
$\therefore \mathrm{AP} \perp \mathrm{PB}$
Since BP is the radius of given circle, so AP has to be a tangent to the circle. Similarly, AQ, BR and BS are the tangents.
6. Construct a pair of tangents to a circle of radius 6.2 cm from an external point 3.8 cm away from the circle.
7. Construct a pair of tangents to a circle of radius 4 cm from an external point 4 cm away from the circle.
8. Construct a tangent to a circle of radius 3.5 cm from a point on the concentric circle of radius 7 cm and measure its length.
9. Construct a pair of tangents to a circle of radius 5.5 cm at the end point of radii. The angle between the two radii is $90^{\circ}$.

## 11. Circle: Theorems.

1. Prove that "the tangent at any point of a circle is perpendicular to the radius through the point of contact".
Solution:

Given: a circle $\mathrm{C}(0, \mathrm{r})$ and a tangent l at point A .
To prove: OA $\perp 1$
Construction: Take a point B, other than A, on the tangent l. join OB. Suppose OB meets the circle in C.
Proof: We know that, among all line segment joining the point 0 to a point on l , the perpendicular is shortest to $l$.
$0 A=O C$ (Radius of the same circle)
Now, OB=0C+BC.
$\therefore \mathrm{OB}>0 \mathrm{C}$
$\Rightarrow O B>O A$
$\Rightarrow 0 A<O B$
$B$ is an arbitrary point on the tangent l. Thus, $O A$ is shorter than any other line segment joining 0 to any point on 1 .
Here $\mathrm{OA} \perp \mathrm{l}$.
2. Prove that "the lengths of the tangent drawn from an external point to the circle are equal".
Solution:
Given: A circle with center O. PA \& PB are two tangents drawn from an external point P.

To prove: $\mathrm{PA}=\mathrm{PB}$

Construction: Join OA, OB \& OP.
Proof: It is known that a tangent is at any point of a circle is perpendicular to the radius through the point of contact.
$O A \perp P A \& O B \perp P B$
In $\triangle \mathrm{OPA} \& \mathrm{OPB},\llcorner O P A=\llcorner O P B$
$\mathrm{OA}=\mathrm{OB} \quad$ (radii)
$\mathrm{OP}=\mathrm{OP} \quad$ (common)
Hence $\triangle \mathrm{OPA}$ is congruent to $\triangle \mathrm{OPB}$. Therefore $\mathrm{AP}=\mathrm{PB}$.

## 12. Pair of linear equations in two variables: Graphical solution.

1. Solve by graphically: $x-y=4 \& x+y=10$.

Solution: $x-y=4$
-(i) \& $x+y=10$
From equation (i), we have the following table:

| $x$ | 0 | 4 | 7 |
| :---: | :---: | :---: | :---: |
| $y$ | -4 | 0 | 3 |

From equation (ii), we have the following table:

| $\boldsymbol{x}$ | 0 | 10 | 7 |
| :---: | :---: | :---: | :---: |
| $\boldsymbol{y}$ | 10 | 0 | 3 |

Plotting this, we have

Here, the two lines intersect at point $(7,3)$ i.e., $x=7, y=3$.

## 2. Show graphically the given system of equations

 $2 x+4 y=10$ and $3 x+6 y=12$ has no solution.Solution: $2 x+4 y=10---------(i) \quad \& \quad 3 x+6 y=12$
From equation (i), we have the following table:

| $x$ | 1 | 3 | 5 |
| :--- | :--- | :--- | :--- |
| $y$ | 2 | 1 | 0 |

From equation (ii), we have the following table:

| $x$ | 2 | 0 | 4 |
| :--- | :--- | :--- | :--- |
| $y$ | 1 | 2 | 0 |

Plot the points $\mathrm{D}(2,1), \mathrm{E}(0,2)$ and $\mathrm{F}(4,0)$ on the same graph paper. Join $\mathrm{D}, \mathrm{E}$ and F and extend it on both sides to obtain the graph of the equation $3 x+6 y=12$.

We find that the lines represented by equations $2 x+4 y=10$ and $3 x+$ $y=12$ are parallel. So, the two lines have no common point. Hence, the given system of equations has no solution.

## 3. Draw the graph of $2 x+y=6$ and $2 x-y+2=0$.

Solution:
We have, $2 \mathrm{x}+\mathrm{y}=6$

$$
\begin{equation*}
2 x-y=-2 \tag{i}
\end{equation*}
$$

From equation (i), we have the following table:

| $x$ | 0 | 3 | 2 |
| :--- | :--- | :--- | :--- |
| $y$ | 6 | 0 | 2 |

From equation (ii), we have the following table:

| $x$ | 0 | -1 | 1 |
| :---: | :---: | :---: | :---: |
| $y$ | 2 | 0 | 4 |

4. Draw the graph of the equations $x-y+1=0$ and $3 x+2 y-12=0$.

Solution: we have $x-y=-1$
$3 x+2 y=12------(i i)$
From equation (i), we have the following table:

| $x$ | -1 | 0 | 2 |
| :---: | :---: | :---: | :---: |
| $y$ | 0 | 1 | 3 |

From equation (ii), we have the following table:

| $\boldsymbol{x}$ | 0 | 4 | 2 |
| :--- | :--- | :--- | :--- |
| $\boldsymbol{y}$ | 6 | 0 | 3 |

Practice: solve the following equations graphically
5. $x+2 y=9 \& 2 x-y=3$.
6. $x-2 y=2 \& 2 x+y=-8$.
7. $x-2 y=-9 \& 3 x+y=1$.
8. $x+2 y=4 \& 6 x+y=13$.
9. $X+2 y=1 \& 2 x+3 y=-1$.
10. $X-2 y=8 \& 2 x-3 y=14$.
11. $x-y=5 \& 2 x+y=-11$.
12. $x+y=-7 \& 2 x-3 y=1$.
13. $x+4 y=2 \& 3 x-6 y=18$.

"If a line is drawn parallel to one side of a triangle to intersect the other two sides in distinct points, the other two sides are divided in the same ratio".

Let ABC be the triangle.
The line $\mathbf{l}$ parallel to $\mathbf{B C}$ intersect $\mathbf{A B}$ at $\mathbf{D}$ and $\mathbf{A C}$ at $\mathbf{E}$.
To prove: $\frac{D B}{A D}=\frac{C B}{\mathrm{AE}}$
Join BE,CD
Draw $E F \perp A B, D G \perp C A$
Since $E F \perp A B$,
EF is the height of triangles ADE and DBE
Area of $\triangle$ ADE $=\frac{1}{2} \times$ base $\times$ height $=\frac{1}{2} \times \mathbf{A D} \times$ EF
Area of $\triangle D B E=\frac{1}{2} \times D B \times E F$
$\frac{\text { areaof } \triangle D B E}{\text { areaof } \triangle A D E}=\frac{1 / 2 \times D B \times E F}{1 / 2 \times A D \times E F} \times \frac{D B}{A D}$
Similarly,
$\frac{\text { areaof } \triangle D B E}{\text { areaof } \triangle \mathrm{ADE}}=\frac{1 / 2 \times C B \times E F}{1 / 2 \times A E \times E F} \times \frac{C B}{A E}$
But $\triangle$ DBE and $\triangle$ DCE are the same base DE and between the same parallel straight line BC and DE.
Area of $\triangle D B E=$ area of $\triangle D C E$
From (1), (2) and (3), we have
$\frac{D B}{A D}=\frac{C B}{A E}$
Hence proved.

## 2. Pythagoras theorem:

In a right angles triangle, the square on the hypotenuse is equal to the sum of the squares on the other two sides.

Data: In $\triangle \mathrm{ABC}, \angle \mathrm{ABC}=90^{\circ}$
To Prove: $\mathrm{AB}^{2}+\mathrm{BC}^{2}=\mathrm{CA}^{2}$
Construction: Draw BD $\perp \mathrm{AC}$.

## Proof: Statement

## Reason

 Compare $\triangle \mathrm{ABC}$ and $\triangle \mathrm{ADB}$, $\angle \mathrm{ABC}=\angle \mathrm{ADB}=90^{\circ}$ $\angle B A D$ is common.$\therefore \triangle \mathrm{ABC} \sim \triangle \mathrm{ADB}$
$\Rightarrow \frac{A B}{A D}=\frac{A C}{A B}$
$\therefore \mathrm{AB}^{2}=\mathrm{AC}$. AD
Compare $\triangle \mathrm{ABC}$ and $\triangle \mathrm{BDC}$, $\angle \mathrm{ABC}=\angle \mathrm{BDC}=90^{\circ}$
(Q Data and construction)
$\angle A C B$ is common
$\therefore \triangle \mathrm{ABC} \sim \triangle \mathrm{BDC} \quad$ (Q Equiangular Triangles)
$\Rightarrow \frac{B C}{D C}=\frac{A C}{B C} \Rightarrow=$ (Q AA similarity criteria)

$$
\mathrm{BC}^{2}=\mathrm{AC} \cdot \mathrm{DC} . . . . .(2)
$$

By adding (1) and (2) we get
$\mathrm{AB}^{2}+\mathrm{BC}^{2}=(\mathrm{AC} . \mathrm{AD})+(\mathrm{AC} . \mathrm{DC})$
$\mathrm{AB}^{2}+\mathrm{BC}^{2}=\mathrm{AC}(\mathrm{AD}+\mathrm{DC})$
$\mathrm{AB}^{2}+\mathrm{BC}^{2}=\mathrm{AC} . \mathrm{AC}=\mathrm{AC}^{2}$
$[\mathrm{QAD}+\mathrm{DC}=\mathrm{AC}]$
$\therefore \mathrm{AB}^{2}+\mathrm{BC}^{2}=\mathrm{AC}^{2}$

## 3. AA similarity Criterion theorem:

"If two triangles are equiangular then their corresponding sides are in proportion"

Data: In $\triangle A B C$ and $\triangle D E F$
(i) $\angle \mathrm{BAC}=\angle \mathrm{EDF}$
(ii) $\angle \mathrm{ABC}=\angle \mathrm{DEF}$

To prove: $\frac{A B}{D E}=\frac{B C}{E F}=\frac{C A}{F D}$
Construction: Mark points ' G ' and ' H ' on AB and AC such that
(i) $\mathrm{AG}=\mathrm{DE}$ and (ii) $\mathrm{AH}=\mathrm{DF}$ Join G and H
Proof:
Compare

Statement
$\triangle \mathrm{AGH}$ and $\triangle \mathrm{DEF}$, $\mathrm{AG}=\mathrm{DE}$ $\angle \mathrm{GAH}=\angle \mathrm{EDF}$ $\mathrm{AH}=\mathrm{DF}$
$\therefore \triangle \mathrm{AGH} \cong \triangle \mathrm{DEF}$
$\therefore \angle \mathrm{AGH}=\angle \mathrm{DEF}$

$$
\begin{aligned}
\text { But } \angle \mathrm{ABC} & =\angle \mathrm{DEF} \\
\Rightarrow \angle \mathrm{AGH} & =\angle \mathrm{ABC}
\end{aligned}
$$

[Axiom - 1]
$\therefore \mathrm{GH}|\mid \mathrm{BC}$ [ If corresponding angles are equal then lines are ||.]
$\therefore$ In $\triangle \mathrm{ABC} \frac{A B}{A G}=\frac{B C}{G H}=\frac{C A}{H A} \quad$ [ third corollary to Thales theorem]
Hence $\frac{A B}{D E}=\frac{B C}{E F}=\frac{C A}{F D}$

## 4. Area Of Similar Triangle:

Prove that "The ratio of the areas of two similar triangles is equal to the square of the ratio of their corresponding sides".

We need to prove that

$$
\frac{\operatorname{ar}(A B C)}{\operatorname{ar}(P Q R)}=\left(\frac{A B}{P Q}\right)^{2}=\left(\frac{B C}{Q R}\right)^{2}=\left(\frac{C A}{R P}\right)^{2}
$$

Now, $\operatorname{ar}(A B C)=\frac{1}{2} \times B C \times A M$
and $\operatorname{ar}(P Q R)=\frac{1}{2} \times Q R \times P N$
So, $\frac{\operatorname{ar}(A B C)}{\operatorname{ar}(P Q R)}=\frac{\frac{1}{2} \times B C \times A M}{\frac{1}{2} \times Q R \times P N}$.
Now, in $\triangle \mathrm{ABM}$ and $\triangle \mathrm{PQN}$,
$\angle \mathrm{B}=\angle \mathrm{Q} \quad($ As $\triangle \mathrm{ABC} \sim \triangle \mathrm{PQR})$
and $\angle \mathrm{M}=\angle \mathrm{N} \quad$ (Each is $90^{\circ}$ )
So, $\triangle \mathrm{ABM} \sim \triangle \mathrm{PQN} \quad$ (AA similarity criterion)
Therefore, $\frac{A M}{P N}=\frac{A B}{P Q} \ldots$
Also, $\triangle \mathrm{ABC} \sim \triangle \mathrm{PQR}$ (Given)
So, $\frac{A B}{P Q}=\frac{B C}{Q R}=\frac{C A}{R P}$.
Therefore, $\frac{\operatorname{ar}(A B C)}{\operatorname{ar}(P Q R)}=\frac{A B}{P Q} \times \frac{A M}{P N}$
[From (1) \& (3)]
$=\frac{A B}{P Q} \times \frac{A B}{P Q} \quad[$ From (2) $]$
$=\left(\frac{A B}{P Q}\right)^{2}$
Now using (3) we get:
$\frac{\operatorname{ar}(A B C)}{\operatorname{ar}(P Q R)}=\left(\frac{A B}{P Q}\right)^{2}=\left(\frac{B C}{Q R}\right)^{2}=\left(\frac{C A}{R P}\right)^{2}$

## APPLICATION OF TRIGONOMETRY

1. Two poles of equal heights are standing opposite each other on either side of the road, which is 80 m wide. From a point between them on the road, the angles of elevation of the top of the poles are $60^{\circ}$ and $30^{\circ}$, respectively. Find the height of the poles and the
distances of the point from the poles.
in Right angle $\triangle \mathrm{ABC}\left\lfloor\mathrm{C}=60^{\circ}\right.$.
$\tan 60^{\circ}=\frac{\mathrm{AB}}{\mathrm{AC}}$
$\frac{1}{\sqrt{3}}=\frac{h}{(80-x)}$
$\sqrt{3}=\frac{h}{x}$
$h=\sqrt{3} \mathrm{x} \rightarrow(1)$

$$
\begin{equation*}
\mathrm{h}=\frac{(80-\mathrm{x})}{\sqrt{3}} \rightarrow \tag{2}
\end{equation*}
$$

From (1) and (2)
$\sqrt{3} x=\frac{80-x}{\sqrt{3}}$
Again in right angle $\triangle \mathrm{PQC}, \angle \mathrm{C}=30^{\circ}$.

$\tan 30^{\circ}=\frac{\mathrm{PQ}}{\mathrm{PC}}=\frac{\mathrm{h}}{(80-\mathrm{x})}$
2. From the top of a 7 m high building, the angle of elevation of the top of a cable tower is $60^{\circ}$ and the angle of depression of its foot is $45^{\circ}$. Determine the height of the tower.

Let $A B$ be the height of tower
$A B=(h+7) m$ and $P Q$ be the height of building
In Right angle $\triangle \mathrm{PQB}\left\lfloor\mathrm{B}=45^{\circ}\right.$

$$
\begin{aligned}
\tan 45^{\circ} & =\frac{\mathrm{PQ}}{\mathrm{BQ}} \\
1 & =\frac{\mathrm{PQ}}{\mathrm{BQ}} \quad[\mathrm{PQ}=7 \mathrm{~m}]
\end{aligned}
$$

$$
\begin{aligned}
\sqrt{3} & =\frac{\mathrm{h}}{\mathrm{PC}} \\
\mathrm{~h} & =\mathrm{PC} \sqrt{3}(\mathrm{PC}=\mathrm{BQ}=7 \mathrm{~m}) \\
\mathrm{h} & =7 \sqrt{3} \mathrm{~m}
\end{aligned}
$$

So, height of tower $=A B=7+h$
$=7+7 \sqrt{3}$

$=7(\sqrt{3}+1) \mathrm{m}$
$B Q=7 m$
Again In Right angle $\triangle \mathrm{APC}\left\lfloor\mathrm{P}=60^{\circ}\right.$
$\tan 60^{\circ}=\frac{\mathrm{AC}}{\mathrm{PC}}$

Let the height of light house be $\mathrm{AB}=$ 75 m and distance between two ships be $\mathrm{DC}=\mathrm{x}$
In Right angle $\triangle \mathrm{ABD}\left\lfloor\mathrm{D}=45^{\circ}\right.$

$$
\tan 45^{\circ}=\frac{\mathrm{AB}}{\mathrm{BD}}
$$

$$
1=\frac{75}{\mathrm{BD}}
$$

$$
\begin{aligned}
\tan 30^{\circ} & =\frac{\mathrm{AB}}{\mathrm{BC}} \\
\frac{1}{\sqrt{3}} & =\frac{75}{\mathrm{BD}+\mathrm{DC}} \\
\frac{1}{\sqrt{3}} & =\frac{75}{75+\mathrm{x}} \\
75+\mathrm{x} & =75 \sqrt{3}
\end{aligned}
$$

$\mathrm{BD}=75 \mathrm{~m}$
In Right angle $\triangle \mathrm{ABC}\left\lfloor\mathrm{C}=30^{\circ}\right.$

$$
\begin{aligned}
& x=75 \sqrt{3}-75 \\
& x=75(\sqrt{3}-1) m
\end{aligned}
$$

4. From a point on the ground 40 m away from the foot of a tower, the angle of elevation of the top of a tower is $30^{\circ}$,the angle of elevation of the top of water tank on top of the tower is $45^{\circ}$. Find (i) height of the tower (ii) depth of the tank
(i) Height of the tower . Depth of the tank is CD.

$$
\begin{aligned}
\tan 30^{\circ} & =\frac{\mathrm{AC}}{\mathrm{AB}} & \tan 45^{\circ} & =\frac{\mathrm{AD}}{\mathrm{AB}} \\
\frac{1}{\sqrt{3}} & =\frac{\mathrm{AC}}{40} & 1 & =\frac{\mathrm{AD}}{40}

$$

5. A tree is broken over by the wind forms a right angled triangle with the ground. IF the broken parts makes an angle of $60^{\circ}$, with the ground and the top of the tree is now 20 m from its base, how tall was the tree.

\frac{1}{2} & =\frac{20}{\mathrm{BC}} & \mathrm{AB} & =20 \sqrt{3} \mathrm{~m} .
\end{aligned}
$$

6. There is a small island in the middle of a 100 m wide river and a tall tree stands on the island . $P$ and $Q$ are points directly opposite to each other on two banks and in the line with the tree . If the angle of elevation of the top of the tree from $P$ and $Q$ are respectively $30^{\circ}$ and $45^{\circ}$ find the height of the tree

$$
\begin{aligned}
& \text { Let } \mathrm{OA} \text { be the tree of height } \mathrm{h} \text { metre. } \\
& \text { In triangle POA and QOA, we have } \\
& \tan 30^{\circ}=\frac{\mathrm{OA}}{\mathrm{OP}} \text { and } \tan 45^{\circ}=\frac{\mathrm{OA}}{\mathrm{OQ}} \\
& \Rightarrow \frac{1}{\sqrt{3}}=\frac{\mathrm{h}}{\mathrm{OP}} \text { and } 1=\frac{\mathrm{h}}{\mathrm{OQ}} \\
& \Rightarrow \mathrm{OP}=\sqrt{3} \mathrm{~h} \text { and } \mathrm{OQ}=\mathrm{h} \\
& \Rightarrow \mathrm{OP}+\mathrm{OQ}=\sqrt{3} \mathrm{~h}+\mathrm{h} \\
& \Rightarrow \mathrm{PQ}=(\sqrt{3}+1) \mathrm{h}
\end{aligned}
$$

$$
\begin{aligned}
& \Rightarrow \quad 100=(\sqrt{3}+1) \mathrm{h}[\because \mathrm{PQ}=100 \mathrm{~m}] \\
& \Rightarrow \quad \mathrm{h}=\frac{100}{\sqrt{3}+1} \mathrm{~m} \\
& \Rightarrow \mathrm{~h}=\frac{100(\sqrt{3}+1)}{2} \mathrm{~m} \\
& \Rightarrow \quad \mathrm{~h}=50(1.732-1) \mathrm{m}=36.6 \mathrm{~m}
\end{aligned}
$$

$$
\text { Hence, the height of the tree is } 36.6 \mathrm{~m} \text {. }
$$
